**Abstract:** The Cerrado Biome is currently classified as one of the most diverse savannas in the world. The anthropic destruction of this biome led the Cerrado to be recognized as one of the world's hot spots for bioconservation. Cerrado *sensu stricto* phytophysiology represents 70% of the original Cerrado biome surface and floristic surveys are basic and important studies for conservation initiatives in these areas. Our survey area is a Cerrado *sensu stricto* of 6 ha attached to the Brazilian Ages Memorial, an open air museum located in Distrito Federal, in the center of the Cerrado biome. Our list counted 222 species of angiosperms, with the families Asteraceae, Fabaceae, Malpighiaceae and Myrtaceae being the richest ones. Our work contributes towards a better understanding of the Cerrado biome and also may help future educational programs in the museum.

**Key words:** Distrito Federal, museum, cerrado

## INTRODUCTION

The Cerrado biome in Brazil is currently classified among the savannas with highest biodiversity in the world, with an estimate in excess of 12,000 angiosperms species (Mendonça et al. 2008). Furthermore, it is also significant in terms of its large surface area, having originally covered 21% of Brazilian territory (Aguar et al. 2004) and for including parts of the three largest hydrological systems of South America in its area (Alho and Martins 1995; Klink 1996).

One of the most remarkable characteristics of the Cerrado vegetation is the great variety of phytophysiology, which are represented by a diversity of forests, savannas and meadows (Ribeiro and Walter 2008). Among the savannas phytophysiology, the Cerrado *sensu stricto* is the most common, occurring in almost 70% of the biome (Eiten 1972).

According to Riberio and Walter (2008), the main

characteristics of Cerrado *sensu stricto* are a defined layer of trees and shrubs, covering between 10% to 60%, and an herbaceous layer approximately 60 cm high. The high species number of this phytophysiology is represented by a great diversity of herbs, subshrubs and shrubs mainly represented by the families Fabaceae, Rubiaceae, Myrtaceae and Asteraceae (Ratter 1997). The destruction of Cerrado *sensu stricto* areas, which has seen more than 50% of its area lost or degraded, has resulted in the Brazilian cerrado being recognized as one of the world hotspots for bioconservation (Felfili and Silva Junior 2001).

The Distrito Federal of Brazil (DF) is located in the center of the Cerrado biome (Figure 1) and has suffered from increasing exploitation of its natural resources.

**Figure 1.** The original area of Cerrado Biome in Brazil (based on Ratter et al. 1997) and the study site location within the biome. DF: Distrito Federal, GO: Goiás state.

After 44 years of occupation, 73.8% of its original Cerrado has already been lost (Felfili 2000). Conservation areas represent 42% of the DF area, but many of these have already been invaded by illegal occupation which has led to biodiversity loss and to the contamination and siltation of rivers (Felfili 2000).

In general, the Cerrado fragmentation has reinforced the importance of creating new conservation areas and, particularly, in preserving the areas that already exist. Knowledge of the Cerrado flora in the Distrito Federal is a significant step in planning and selecting new representative areas of the biome that will be prioritized for conservation and recovery (Felfili et al. 1993; Mendonça et al. 2008). Therefore, works like this are very useful towards a better understanding of areas where limited information is available. In addition to that, floristic surveys are a tool to improve herbarium collections, which then will constitute the basis of studies in taxonomy, biogeography and ecology.

## MATERIALS AND METHODS

### Study site

The Brazilian Ages Memorial (in Portuguese “Memorial das Idades do Brasil”) is a privately owned open air museum located at 15°77' S, 047°80' W, on the boundary of Paranoá city, Distrito Federal, Brazil. The area is a memorial about the ancient people who inhabited the region of the central Brazilian highlands and is frequently visited by school groups.

According to the official website (<http://www.paulobertran.com.br>), the area was given this name because it represents the “three ages” of the central highlands formation. The first age is the “geological age”, represented by the rocks and stones, some of them up to 1 billion years old and originally under the Pangean sea. The second is the “anthropological age”, represented by reproductions of ancient cave paintings made by local artists (Figure 2). The third age is the “plant age”, represented by the trails through the area of Cerrado *sensu stricto* in which the survey was done.

**Figure 2.** Cave painting reproductions from the site.

**Figure 3.** Aerial view of the Brazilian Ages Memorial and region on Google Earth™. a) Area in which our floristic survey was done; b) Brazilian Ages Memorial museum; c) *Pinus* sp. plantation.; d) Paranoá Lake.

The site of study is a Cerrado *sensu stricto* located at an altitude of 1,050 m with approximately 6 ha attached to the Brazilian Ages Memorial Museum. The site is close to a large plantation of *Pinus* sp. which has already started to invade the area’s native vegetation via seed dispersal (Figure 3).

### Data collection

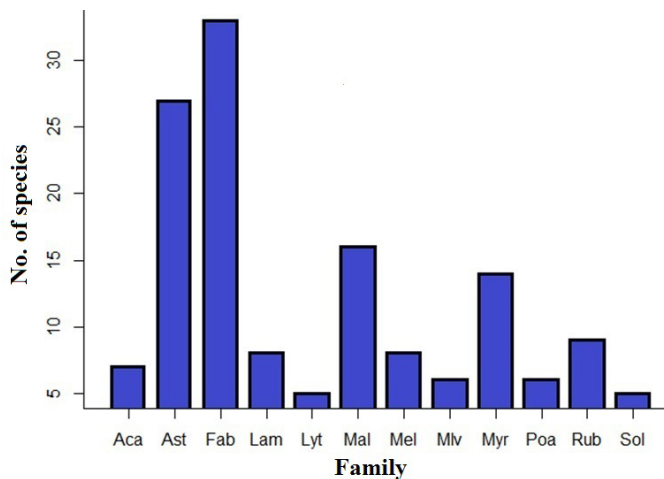

Our species list was mostly defined by weekly collections over a period of a year, from May 2009 to May 2010. Collections made by the Ethnobotany course of the University of Brasilia, conducted by Prof. Carolyn E. B. Proença in 2009, were also included in our survey. Some sporadic collections made in the following years were also considered. The collections were made mainly next to the trails and fertile plants with buds, flowers and fruits were prioritized. Some characteristics of the plants, such as color, scent and latex were also recorded and are available in BRAHMS at the University of Brasilia Herbarium (UB).

The species identification was mostly made by comparison with dry specimens in the UB herbarium. In some cases, species were also identified using specialized keys, literature, and consulting taxonomists. The collected material was incorporated into the UB collection.

Synonyms follow the classification listed on the Flora do Brasil website (Lista de Espécies da Flora do Brasil, consulted in 2015), for it presents the most up to date classification of plants in Brazil. The family classification system follows the Angiosperm Phylogeny Group III (APG III 2009). Classification of the species as native or invasive was the same as used by Mendonça et al. (2008). Information of habit (i.e., shrub, tree) was also taken from the “Espécies da Flora do Brasil” website (consulted in 2015) and from Mendonça et al. (2008).

## RESULTS

Our floristic survey counted 222 species of angiosperms, representing 148 genera and 59 families,

**Figure 4.** Families with the number of species in the Brazilian Ages Memorial. Aca = Acanthaceae; Ast = Asteraceae; Fab = Fabaceae; Lam = Lamiaceae; Lyt = Lythraceae; Mal = Malpighiaceae; Mel = Melastomataceae; Mlv = Malvaceae; Myr = Myrtaceae; Poa = Poaceae; Rub = Rubiaceae; Sol = Solanaceae.

of which 50 are eudicots, 8 are monocots, and one is a magnoliid (Annonaceae). The complete species list, with collection number, habit, category (if endemic or invasive) is presented in Table 1.

Family with the largest species number in the area was Fabaceae (represented by 32 species), followed by Asteraceae (27 species), Malpighiaceae (16 species), Myrtaceae (13 species), Rubiaceae (9 species), Melastomataceae and Lamiaceae (8 species each), Acanthaceae (7 species), Poaceae and Malvaceae (6 species each), Lythraceae and Solanaceae (5 species each) (Figure 4).

Among the genera, the richest in species number were *Banisteriopsis* (Malpighiaceae) with seven species, *Chamaecrista* (Fabaceae), *Eugenia* (Myrtaceae) and *Miconia* (Melastomataceae) with six species each, *Byrsonima* (Malpighiaceae), *Hyptis* (Lamiaceae) and *Myrcia* (Myrtaceae) with five species each, and *Mimosa* (Fabaceae) represented by four species.

## DISCUSSION

The high diversity of Asteraceae and Fabaceae species was expected since these are among those families considered hyperdiverse in Brazil (Rapini et al. 2009). They also appear as the two most diverse species of eudicots in other surveys in similar areas of Cerrado (Carvalho et al. 2010; Ishara and Rodela 2012).

The families Poaceae and Cyperaceae usually are represented by a high species number in Cerrado *sensu stricto* environments (Ratter et al. 1997). In our study, however, we found only three species of Cyperaceae and six of Poaceae, a number abnormally low. This result can be explained by either (1) the families were poorly sampled or (2) because the site is small and well-cared for, there was no sign of recent fire in the area. Amaral et

al. 2013, by analyzing an area of Cerrado also in Distrito Federal, found that the absence of fire in Cerrado leads to an increasing in the number of woody species and a decreasing in the number of herbaceous plants, such as grasses, what could explain the little diversity of these families in the area.

Myrtaceae and Malpighiaceae families, the third and fourth most diverse families in our survey, also appear in similar studies between the most diverse families in Cerrado *sensu stricto* areas (Carvalho et al. 2010; Ishara and Rodela 2012) confirming the great ecological importance of these two families in the biome.

Among the listed species, *Anemopaegma arvense* (Bignoniaceae) is cited as endangered by Martinelli and Moraes (2013). *Caryocar brasiliense* (Caryocaraceae) is cited in the same literature as a species with commercial value undergoing distribution decline. These threatened species are concerning as the area has already been invaded by individuals of *Pinus* sp. Furthermore, six species are not cited in the books of the Flora do Distrito Federal (Cavalcanti et al. Vols. 1 to 10, from 2001 to 2012) nor in the Flora do Brasil website for Distrito Federal (Lista de Espécies da Flora do Brasil, consulted in 2015) (Table 1), highlighting that the flora of DF, although confined to small preserved areas, requires additional study.

Our study concludes that the Brazilian Ages Memorial, while not a conservation area, is an area of ecological relevance to the Distrito Federal. The area is rich in native species of Cerrado *sensu stricto* vegetation, which in turn attracts species of fauna associated with this kind of vegetation. Furthermore, it is an area suitable for new studies that will contribute to its management and conservation. This list can also be used for ethnobotanical studies in order to make the link between the “anthropological age” and “plant age” at the museum. Additionally, it will improve the educational purposes of the Memorial of Brazilian Ages.

## ACKNOWLEDGEMENTS

We would like to acknowledge André Bertran, for help and making the study site available, and the Foundation for Research Support of Federal District (FAP-DF), the body responsible for funding this project. We would like also to thank Petra Broddle for comments on the manuscript and Regina Célia de Oliveira for helping with identification.
